# ITRF Measurement Techniques

ITRF

NDM

Required by GPS

Semi dynamic datum

No deformation model

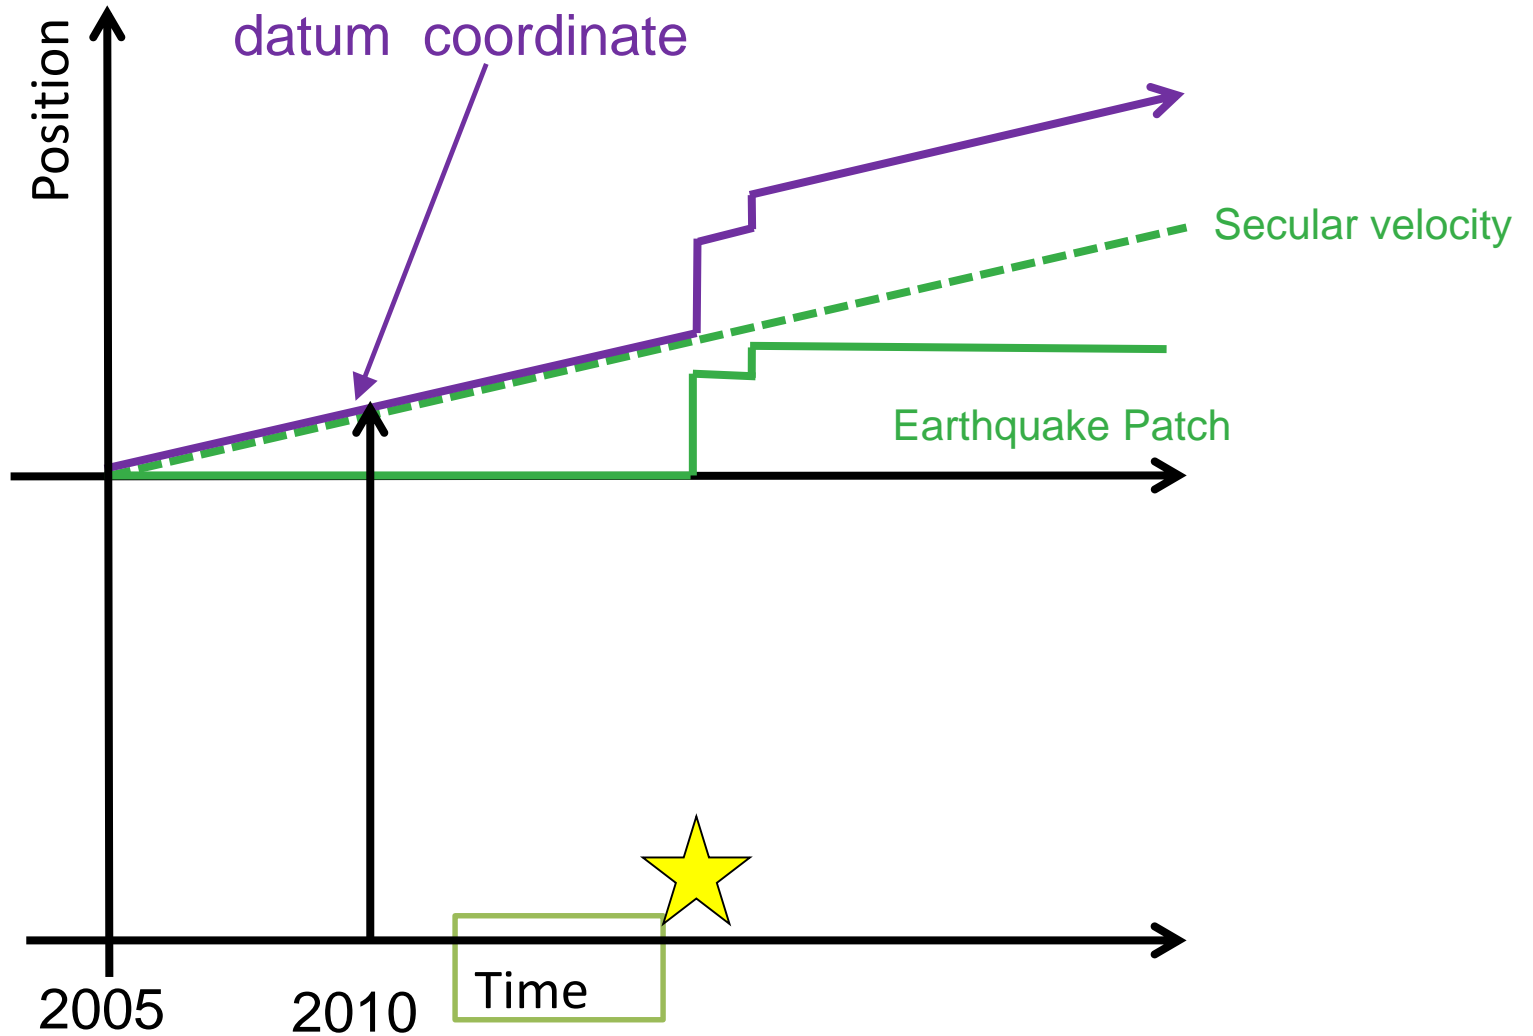

Datums and epoch dates change frequently

Stable coords

deformation model

Semi dynamic datums are aligned with the ITRF Coordinates transformed reference epoch using the national deformation model

# How the NDM works

# Problem with coordinates

- Using emerging technologies like Precise Point Positioning PPP and commercial PPK service (real time) cm level positioning is available is available globally.
  - However these are in coordinates in the ITRF represent the instantaneous position of the point the epoch of observation
- But almost all applications for precise coordinates require coordinates at particular time up to 20 years in the past.

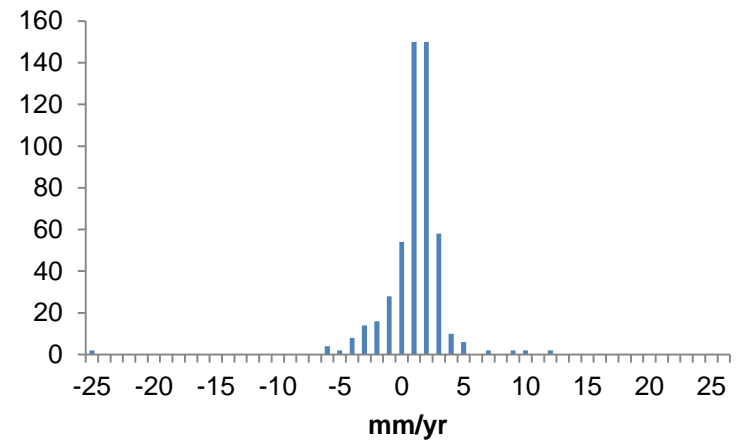

# ITRF2008 Velocity Residuals

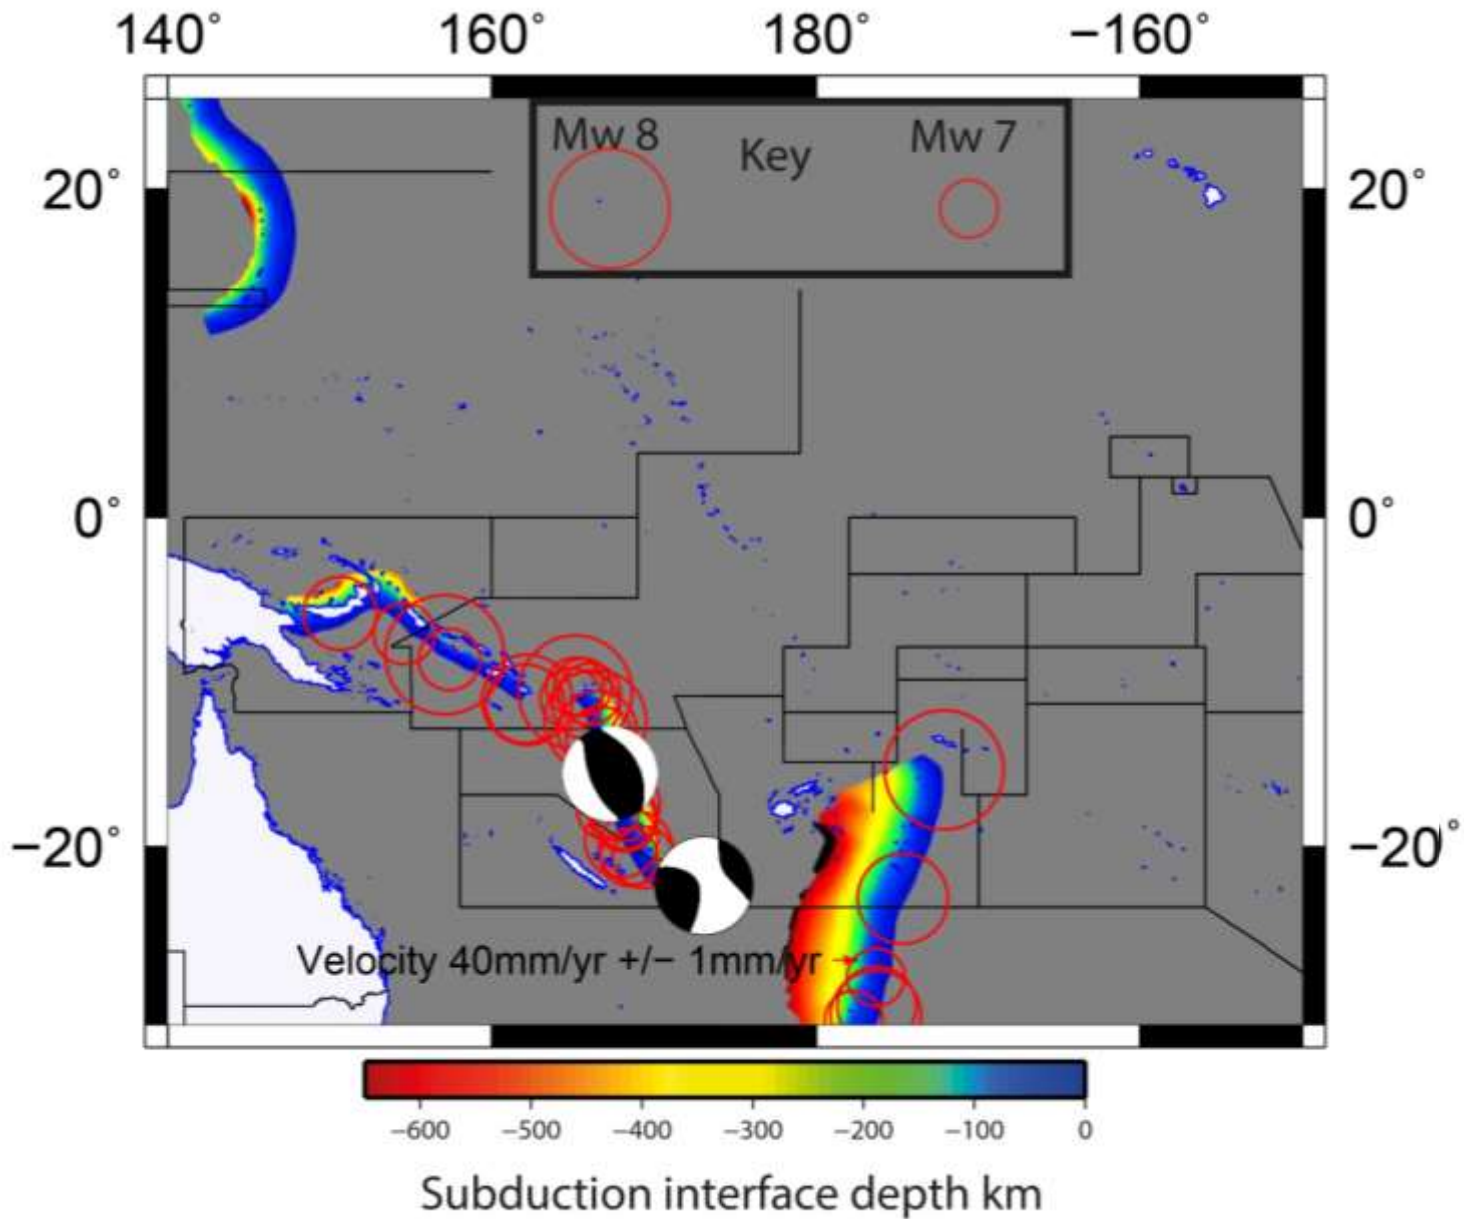

## East Residuals

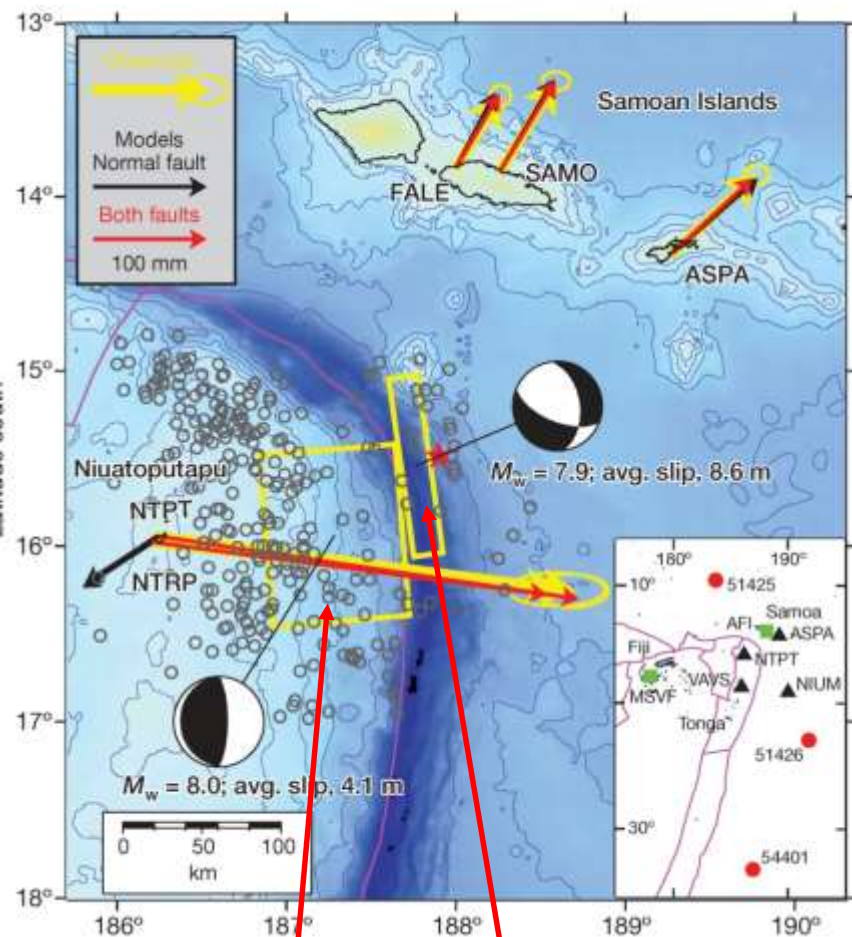

## North Residuals

# Tongan Earthquake of September 2009

Thrust EQ

Normal EQ

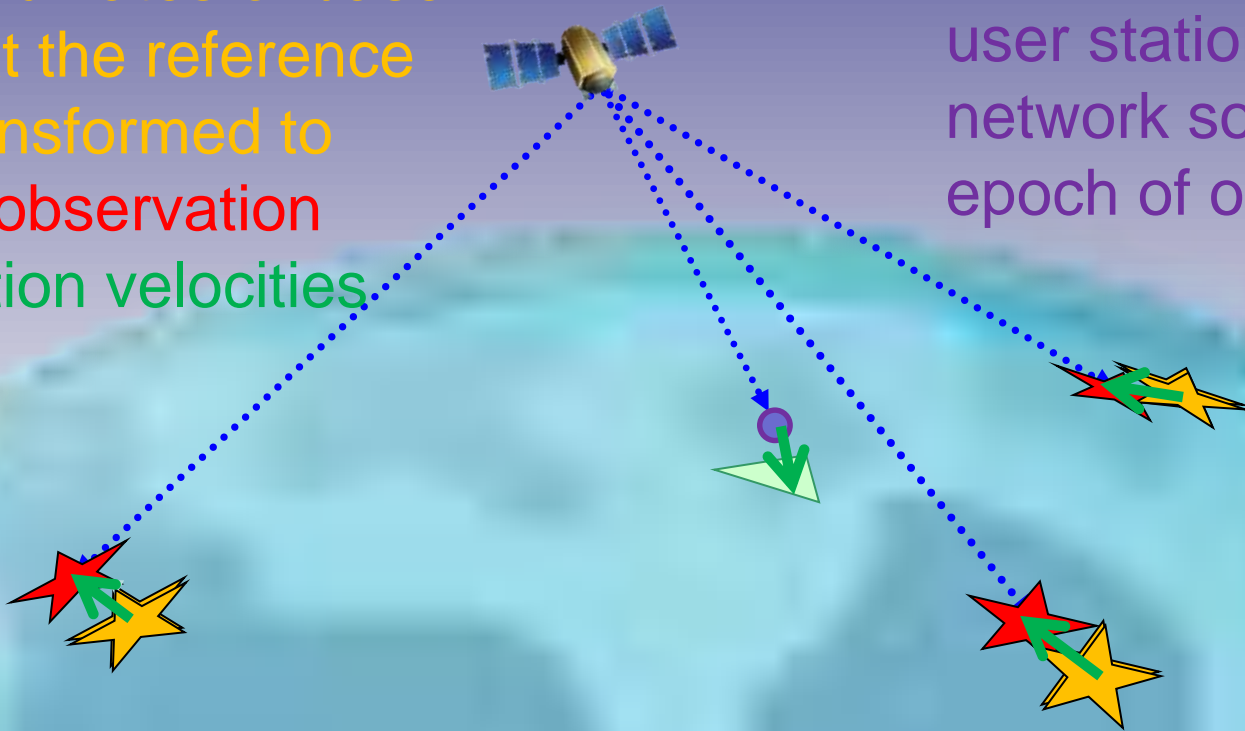

# Summary of PPP, PPK and AUSPOS processing

ITRF coordinates at reference epoch transformed to epoch of observation

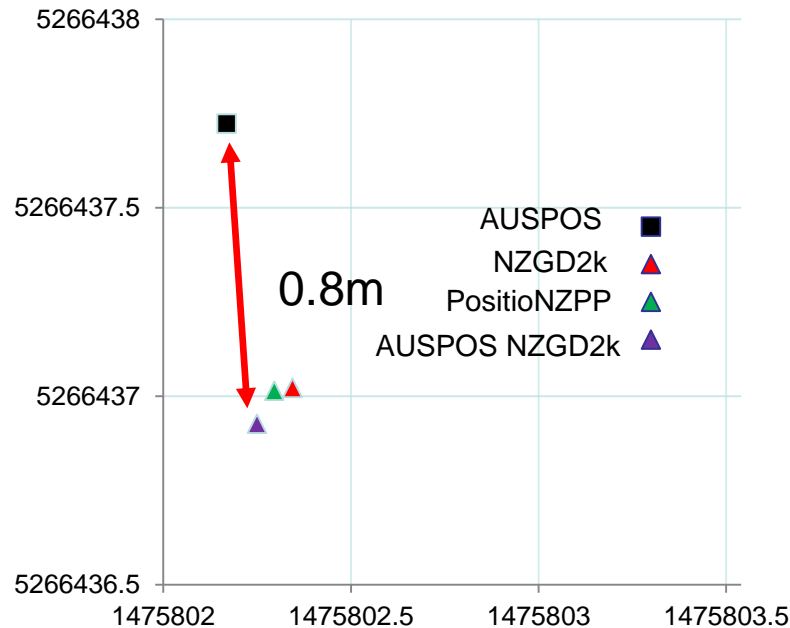

ITRF coordinates of base stations at the reference epoch transformed to epoch of observation using station velocities

ITRF coordinates from user station from a network solution at epoch of observation

ITRF coordinates need to be projected from epoch of observation to the reference epoch using NDM

# Coordinate comparison

- All PPP and most Network RTK coordinates are actually in the ITRF datum at the epoch of observation
- Occurs because none of the commercial codes presently apply the deformation model
  - Produces nearly 1 m shift in vs NZGD2000 in New Zealand
  - On line position services like PositionNZ-PP do apply their national deformation model
  - Currently PPP and PPk users have to manually apply the deformation models

# Conclusions

- The use of emerging technologies means that cm level positioning is available globally to the public.
  - Use of these positions require the development of accurate models to correct for crustal deformation
  - Our study indicates that a global velocity field model provide a reasonable estimate of the secular velocities but in rapidly deforming areas it is not accurate enough for geodetic purposes
  - Earthquakes are more of a problem. Future work should focus on the timely development of earthquake patches.
